AN UNUSUAL CASE OF A PATIENT WITH EXTREME FIXED NECK FLEXION PRESENTING FOR EMERGENCY ABDOMINAL SURGERY

MICHAEL OLEYAR* AND STEVEN M NEUSTEIN**

Abstract

Patients with a known difficult airway for intubation who present with intestinal obstruction are at an increased risk for receiving general anesthesia. It may be necessary to perform an awake fiberoptic intubation, or possibly a tracheostomy if an awake intubation cannot be performed. In some cases, an awake tracheostomy may not be possible due to the anatomy. We report a case in which a patient with extreme fixed neck flexion deformity in whom a tracheostomy would not have been possible, presented for emergency abdominal surgery.

Case Report

A 77 year-old man presented for emergency herniorrhaphy of an incarcerated left inguinal hernia with small bowel obstruction. He was complaining of nausea and vomiting. Past medical history included arthritis, hypertension, Parkinson’s disease, enlarged prostate and colorectal cancer s/p chemotherapy and radiation therapy. Medications included finasteride, carbidopa/levodopa, and mirtazapine.

On physical exam, his neck was in a 90 degree flexed position, and was immobile. He did have a good mouth opening, and his airway classification was Mallampati 3. His thyromental distance was 6 cm. His abdomen was distended, and he had an incarcerated left inguinal hernia.

Once in the operating room, he was propped up on a ramp created with pillows and padding.

Fig. 1
The patient is positioned for surgery, with padding to stabilize the head in a vertical position. The chin is juxtaposed on the chest. The nasotracheal tube is in position.
Glycopyrrolate 0.2 mg was administered to decrease secretions. Airway topicalization was accomplished with the use of 4% lidocaine by nebulizer and then atomizer. It was not possible to perform a cricothyroid puncture for tracheal anesthesia, due to the extreme neck flexion. The nares were prepped with lidocaine/phenylephrine.

The nasal passageway was then dilated with a 6.0 nasal airway which had been lubricated with 2% viscous lidocaine. Following removal of the nasal airway, a 7.0 ID soft nasotracheal tube (Portex, Kenne, NH) was passed via the nares into the pharynx. While standing in front of the patient, the fiberscope was passed through the endotracheal tube. Once the patient’s vocal cords were visualized, an epidural catheter was advanced via the working channel of the fiberscope, and 4 ml of 4% lidocaine was administered via the epidural catheter. The fiberscope was then advanced into the trachea, and the endotracheal tube was passed over the fiberscope into the trachea. General anesthesia was then induced. Following completion of surgery, the patient was extubated, and had a good recovery. A photograph of the patient following tracheal intubation and induction of anesthesia can be seen in the Fig. 1.

Discussion

Extreme neck flexion may cause difficulty with endotracheal intubation. We have described an unusual case of a patient with a severe fixed flexed neck deformity, presenting for emergency surgery. A tracheostomy was not possible. A cricothyroid puncture for transtracheal topicalization was also not possible.

Awake fiberoptic intubation appeared to be the safest technique. The technique of passing an epidural catheter through the working channel of the fiberoptic bronchoscope was utilized, which has been previously described.
